TITLE: Infrared absorption spectra of some metal chlorates

PERIODICAL: Referativnyy zhurnal, Fizika, no. 1., 1962, p., abstract 11V14.  
("An. Univ.", I. I. Parhon", Ser. ştiinţ. natur.", 1961, v. 1.,  
no. 4, p. 1 - 11, Romanian; summaries in Russian and French.)

TEXT: Infrared absorption spectra were obtained in the  $400 - 1400 \text{ cm}^{-1}$  range for chlorates of the Na, K, Rb, Cs, Sr, Ba, and Ag metals ; prepared in the form of suspensions in nujol and hexachlorobutadiene. The spectroscopic data obtained permit the assumption that in the case of alkali metal chlorates the anion ( $\text{ClO}_4^-$ ) has the symmetry of point group  $C_{3v}$ . As to the remaining chlorates investigated it appears that the anion, in consequence of the partly covalent character of the metal-anion bond, has the symmetry of point group  $C_s$ . There are 24 references.

Orig Pub: Dekl. AN ArmSSR, 1956, 23, No. 1, 23 - 28.

Abstract: The authors give an account of views of various investigators on the mechanism of acetylene (I) polymerization and assume that the mechanism of I polymerization in presence of  $Cu^+$  is an ion mechanism: first the  $\pi$ -complex of I is formed in the result of the addition of I to  $Cu^+$ , this complex is converted into a carbonium ion, which is stabilized later by producing the  $\pi$ -complex of vinylacetylene. The latter

2017 RELEASE UNDER E.O. 14176

SOURCE: AN ArmSSR Izvestiya Khimicheskiye nauki, v. 17, no. 5, 1964, 513-516

TOPIC TAGS: vinylmethylicarbinol dehydration, espatit dehydrator, cation exchange resin, catalytic dehydration, vinylacetylene/espatit resin KU-1H plus

ABSTRACT: Due to the unsatisfactory results of the dehydration of tertiary vinyl-ethynyl carbinols by heating them with strong acids, the authors investigated their dehydration with the espatit KU-1H cation exchange resin. By heating the above alcohols for 5-6 hrs. at 65-70°C together with the above cation exchange resin, excellent yields of the corresponding dienines (up to 85%) were achieved. Especially good results could be obtained by distilling the diene while it was being formed. The operation is then considerably shorter (30-35 min), no resins or byproducts being formed. If distillation is not used, the cation exchange resin can be separated by filtration or decantation. The resin can be reused many times both in the laboratory and in industry. The following carbinols were dehydrated: dimethylvinylethyne carbinol, methylethylvinylethyne

[Bull. Moscow Inst. of Steel]. Doklady Akad. Nauk S.S.R.  
112, 330-9 (1967) Feb. 1. (In Russian)

A specially prepared steel containing 1.05% C, 11.00% Cr,  
and 0.012% H was investigated to determine the internal  
friction dependence on temperature. The analysis of thermal  
treatments of the samples at various temperatures up to  
1200° is given in graphical form. Tables of lattice param-  
eters and phase structures are included. (III, V.J.)

S/126/62/013/005/027/031  
E073/E535

AUTHORS: Shapochkin, V.A. and Pirigova, L.B.  
TITLE: Influence of temperature on the shear under pressure  
PERIODICAL: Fizika metallov i metallovedeniye, v.13, no.5, 1962,  
705-737

TEXT: The change in the shear resistance with increasing average normal stress at various temperatures was investigated on a test machine which ensured that measurements were under conditions approximating hydrostatic pressure. The part of the test apparatus containing the sample was placed into a thermostat which enabled lowering the temperature to -50°C. Heating apparatus was also provided whereby the highest heating temperature was 200°C. Tin, lead, zinc, cadmium, indium and other low melting point metals were tested at pressures between 0 and 100 000 kg/cm<sup>2</sup>. Curves of the shear resistance  $\tau$  as a function of the pressure  $p$  were obtained for various temperatures. In the same way as curves obtained at room temperature, these curves consist of two sections - the initial, corresponding to external friction caused by sliding between the piston and the specimen

Card 1/3

Influence of temperature on the ... S/120/02/013/005/027/071  
B073/E535

surface, and the section corresponding to internal shifts when the slip at the contact surface stops and slip occurs inside the material. For a number of substances the shear force increased considerably with temperature at the initial part of the  $\tau$  vs.  $p$  curve and this is explained by an increase of the friction coefficient with increasing temperature. As the pressure increases further and there is a change over from external to internal sliding, the shear resistance at elevated temperatures becomes lower than at room temperature. At pressures of the order of 100 000 kg/mm<sup>2</sup> and test temperatures of 200°C, the shear resistance of a number of metals drops by a factor of 4. Simultaneously there will be a displacement of the zone of change over from external friction to internal sliding towards lower pressures. The  $\tau$  vs.  $p$  curves for elevated temperatures form a divergent beam. With increasing temperatures the influence of hydrostatic pressure on the shear resistance decreases. At low temperatures the opposite picture is observed, the initial section of external friction lengthens and the shear resistance increases. The curves form a more divergent beam than in the case of

Card 2/3

S/126/62/013/005/027/031

E073/E535

Influence of temperature on the ...

elevated temperatures. For the materials investigated the shear resistance at a pressure of 10000 kg/cm<sup>2</sup> increased by a factor of 2 for a temperature drop from room temperature to -50°C. Those metals which had a lower shear resistance at room temperature proved to be more sensitive to changes in the shear resistance at low temperatures. There are 2 figures.

AUTHOR: Kunnev, St., Pirinchieva, R., and Marinova, Kr.TITLE: Distribution of the potential and movement of minority current carriers  
in Cds single crystalsSOURCE: Bulgarska akademiya na naukite. Fizicheski institut, Izvestiya na  
Fizicheskiy institut s ANEB, v. 10, no. 2, 1962, 13-27TOPIC TAGS: potential, electric potential, potential distribution, current  
carrier, minority current carrier, electrode, Cds single crystal, hole, space  
charge, minority carrierABSTRACT: Distribution of electric potential in Cds single crystals has been  
investigated along lines in which previous experimental and theoretical contribu-  
tions are very few. It has been found that the potential distribution along the  
length of crystals shows a sharp drop near the anode. In addition, as the authors  
have shown in a previous short report (Dokl. BAN, 13, No. 6 (1960)), when an  
intermediary metal strip is placed between the two basic electrodes, as shown  
in Fig. 1 of the Enclosure 1, and a narrow beam of light is introduced between

Card 1/3

L 18460-63

ACCESSION NR: AT3002407

O

the strip and the anode, the electric potential of the strip assumes abnormally high values in comparison with the other parts of the crystal. Such positive charging of the intermediary strip is observed in the dark as well, but only for crystals which have rectification volt-ampere characteristics (see Fig. 2 of Enclosure 2). The above peculiarities disappear (viz. the distribution of potential does not show the presence of barrier layers, nor is charging of the intermediary strips observed) if prior to the placing of the electrodes and the intermediary strips the crystal is heated in vacuum or treated in gas discharge. It is demonstrated that the phenomena observed depend on peculiarities in the layers at the electrodes, and not on the type of electrode material but on the gases absorbed on the surface. From infra-red radiation experiments it is assumed that the movement of a positive space charge determined by the holes optically created or injected by the anode plays a basic part in the phenomena studied. It is assumed that the movement of the holes and their shift to comparatively great distances in the CdS single crystals is of essential importance to the electric processes in the crystals. It is shown that the positive charging

of the intermediary strip may be used as one of the few existing methods of studying the behavior of the minority current carriers in CdS and probably for determining the values characterizing these carriers. Orig. art. has: 15 figures.

TITLE: Investigation of the luminescence spectra of Er<sup>3+</sup> in mixed Y<sub>2</sub>O<sub>3</sub>, In<sub>2</sub>O<sub>3</sub> and Sc<sub>2</sub>O<sub>3</sub> crystals /Report, Fourteenth Conference on Luminescence held in Riga 16-23 September 1965/

SOURCE: AN SSSR. Izvestiya. Seriya fizicheskaya, v. 30, no. 4, 1966, 713-715

TOPIC TAGS: luminescence spectrum, mixed crystal, erbium, yttrium compound, indium compound, scandium compound

ABSTRACT: The work was undertaken in view of the fact that for studying luminescence centers and the factors that affect the luminescence spectrum it is of value to investigate the influence of the intracrystal fields acting in the vicinity of the centers. The intracrystal fields can be varied by introducing the activator into solid solutions with the same type of lattice but different values of the lattice constant. Specifically, the present work was devoted to detailed investigation of the effect of changes of the intracrystal field on the luminescence of Er<sup>3+</sup> ions in mixed I<sub>2</sub>O<sub>3</sub>-In<sub>2</sub>O<sub>3</sub> and Y<sub>2</sub>O<sub>3</sub>-Sc<sub>2</sub>O<sub>3</sub> crystals. The spectrum of Er<sup>3+</sup> in Y<sub>2</sub>O<sub>3</sub> was investigated earlier by the

authors (*Optika i spektroskopiya*, In press, 1986) and was fully interpreted by P. Kislink, W.F.Krumke and J.B.Gruber (*J.Chem.Phys.*, 40, 3606, 1964). Yttrium, indium and scandium oxides all crystallize in a body-centered cubic lattice of the  $Mn_2O_3$  type. The lattice constant of mixed crystals varies in the range of 5% in the  $Y_2O_3$ - $In_2O_3$  system and in the range of 8.2% in the  $Y_2O_3$ - $Sc_2O_3$  system. X-ray diffraction studies indicated that continuous series of solid solutions form in these systems. The shift of the luminescence lines of  $Er^{3+}$  and the shifts of the corresponding levels in mixed crystals of the  $Y_2O_3$ - $Sc_2O_3$  system are shown in a figure. Another figure characterizes the variation of the line width of  $Er^{3+}$  as a function of the concentration of the second component in the  $Y_2O_3$ - $Sc_2O_3$  and  $Y_2O_3$ - $In_2O_3$  systems. Variation of the component concentration, in addition to shift and broadening of the lines, leads to change of the shape of the lines, i.e., development of strong asymmetry at concentrations of up to 10% of the second component. The number of lines in both the absorption and the luminescence spectrum remains unchanged, which means that under the given experimental conditions in the investigated crystals inversion centers do not disappear and the forbiddenness on the electric dipole transitions from  $C_{31}$  sites is not removed. TITLE: Effect of the concentration of Er<sup>3+</sup> on its spectrum in Y<sub>2</sub>O<sub>3</sub>

SOURCE: Optika i spektroskopiya, v. 21, no. 3, 1966, 319-321

TOPIC TACS: erbium, yttrium compound, line intensity, line width, emission spectrum, line broadening

ABSTRACT: The dependence of the line intensities and widths in the emission spectrum of Er<sup>3+</sup> activator in Y<sub>2</sub>O<sub>3</sub> on the Er<sup>3+</sup> concentration (0.01 to 10 mole %) was studied; in particular, the effect of Er<sup>3+</sup> concentration on three main groups of lines corresponding to transitions from ^3H<sub>1/2</sub> level to ^4S<sub>1/2</sub> level and from ^3H<sub>5/2</sub> and ^3F<sub>7/2</sub> levels to the ground level. The study was conducted at 77 and 295°K. Fig. 1 shows Er<sup>3+</sup> concentration versus the transmission of certain lines belonging to the main groups: ^2H<sub>11/2</sub> → ^4I<sub>15/2</sub> = 3196 Å (line 1), ^2H<sub>9/2</sub> → ^4I<sub>15/2</sub> = 5421.5 Å and 5501.5 Å (lines 2 and 3); ^2H<sub>5/2</sub> → ^4I<sub>15/2</sub> = 5525 Å (line 4). Above 1 mole % Er<sup>3+</sup>, considerable narrowing of the broadening is observed whose course and magnitude is the same for all lines of the ^3S<sub>1/2</sub> - ^4I<sub>15/2</sub> group. The effect of activator concentration on transitions from different upper levels is different. A change in temperature from 77 to 295°K causes a decrease of line intensities in the ^4S<sub>3/2</sub> → ^4I<sub>15/2</sub> and ^2H<sub>11/2</sub> → ^4I<sub>15/2</sub> groups. A rise-

Card 1/2

ing  $\text{Er}^{3+}$  concentration changes the half-widths  $\delta$  of the emission lines. Fig. 2 shows these changes for four lines of the  ${}^4\text{S}_{3/2} - {}^4\text{T}_{15/2}$  group. Up to 1 mole %  $\text{Er}^{3+}$ , the line width does not change; above this concentration, a broadening which is different for different lines is observed. This broadening is thought to be governed by a resonance mechanism. From the concentration quenching and line broadening data it is concluded that 10 Å is the minimum distance between closest  $\text{Er}^{3+}$  at which an appreciable interaction between these ions begins to take place. Orig. art. has 2 figures.

2477. TWO-STAGE SLUDGE REMOVAL. Mirin, I. (Zheleznodorozhni Transport, 1947, No. 4, 77-9; Engrs., Dig., Dec. 1947, No. 415-7). Sludge due to chemical treatment of feedwater used by a locomotive is usually removed by the periodical blow-down of the boiler. The author remarks that a more effective method of sludge removal which reduces water loss is required and proposes a device for sludge removal which suggests a novel solution of the problem. The principle of the system described depends upon the use of the water circulation so that the rate of sludge removal rises with the evaporation. Details and drawings of two designs of sludge collector suggested by the author are given.
